

Postoptimality Analysis with Multivalued Decision Diagrams

Tarik Hadzic

IT University of Copenhagen

John Hooker

Carnegie Mellon University

Cork Constraint Computation Centre

June 2008

Motivation

- **Perform postoptimality analysis** for 0-1 programming.
- **Problem:** It is hard to reason about the entire solution space.
- **Solution:** Represent the set of near-optimal solutions as a Binary Decision Diagram.
 - This was done in previous work (H&H 2006).

Motivation

- Today's focus: **Scalability**
 - How large do BDDs grow with problem size?
 - How can we minimize the growth?
- We introduce **sound** BDDs.
 - Much **smaller** than the full BDD.
 - Provide **exact** postoptimality analysis for near-optimal solutions.

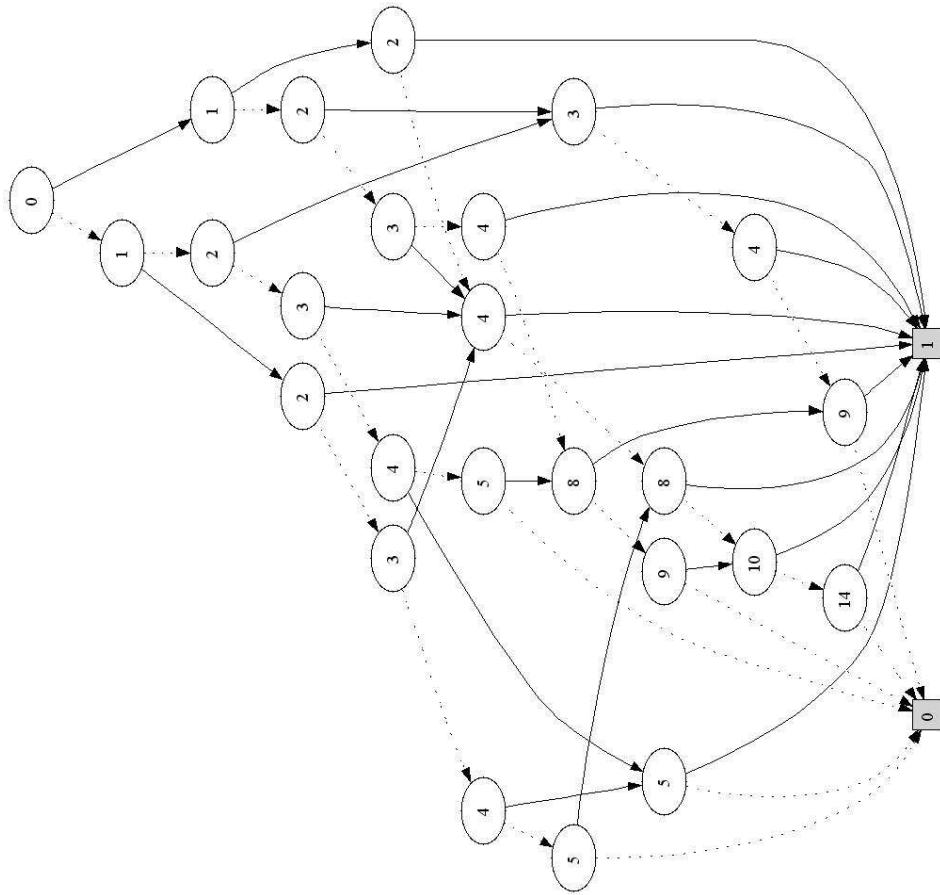

This slide can currently be expanded.

Types of Analysis

- Characterization of optimal or near-optimal solutions.
 - How much freedom is there to alter solution without much sacrifice in solution quality?
- Sensitivity analysis.
 - Which problem data significantly affect the solution?
- Online what-if queries.
 - What if I fix certain variables?

Basic idea

- Use **reduced ordered binary decision diagrams** (BDDs) as a compact representation of the set of feasible or near-optimal solutions.
 - We can extract information from BDDs in real time.
 - Although exponentially large in the worst case, BDDs can be compact for important constraints.

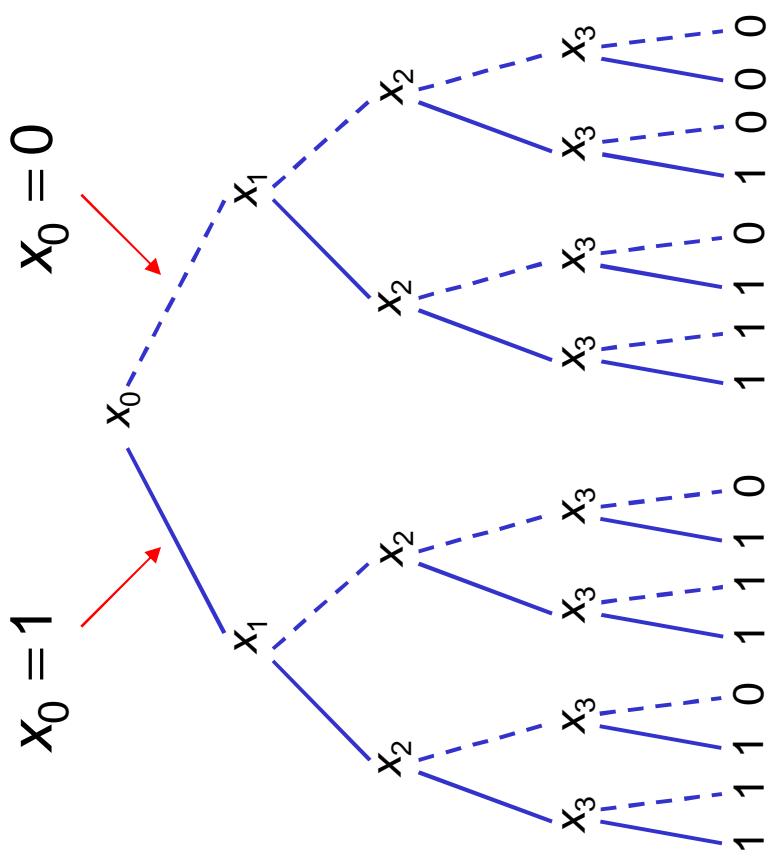

Binary Decision Diagrams

- A reduced ordered BDD for a constraint set is a **compact representation of the branching tree** for a given branching order.
 - If both branches from a node lead to identical subtrees, remove the node.
 - If two subtrees are identical, superimpose them.

Branching tree for 0-1 inequality

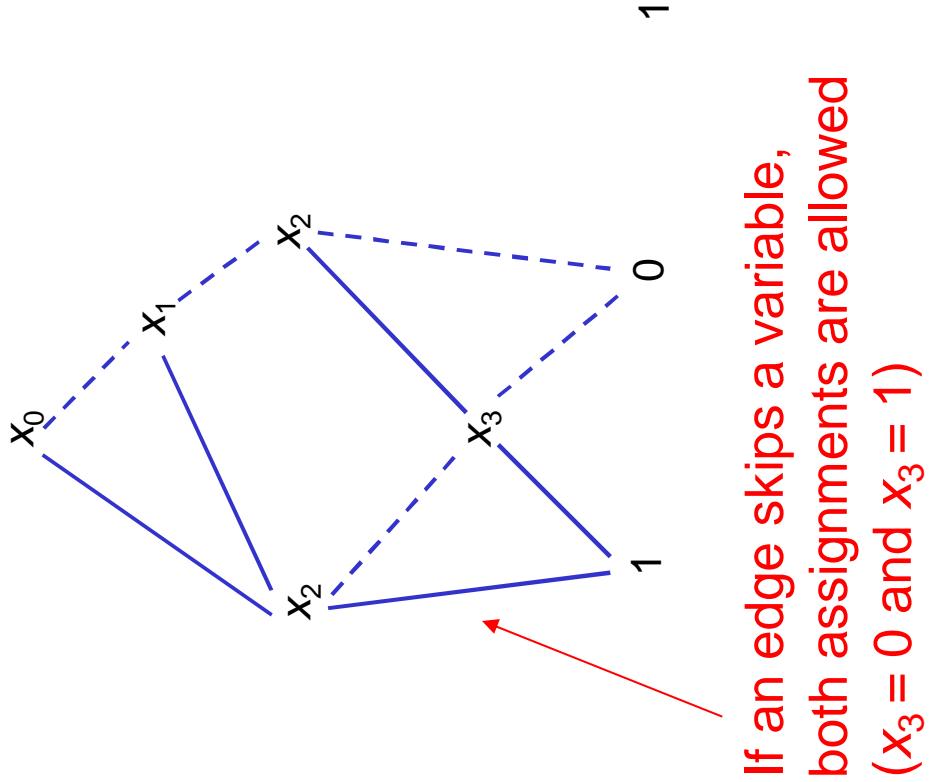

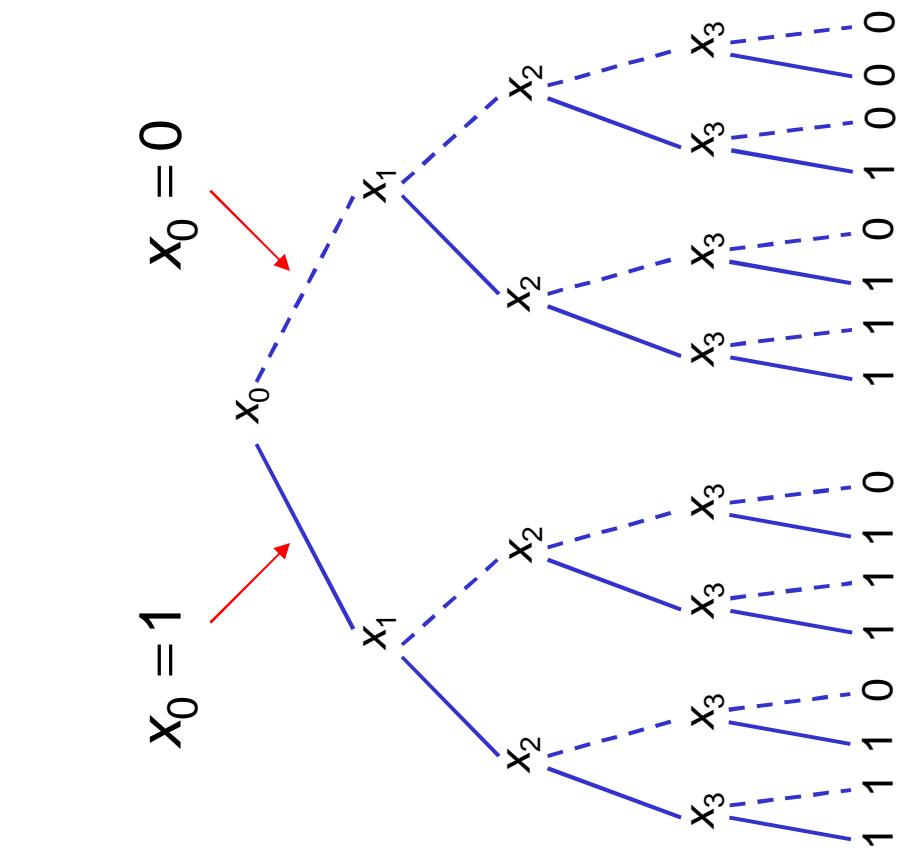

$$2x_0 + 3x_1 + 5x_2 + 5x_3 \geq 7$$

Branching tree for 0-1 inequality

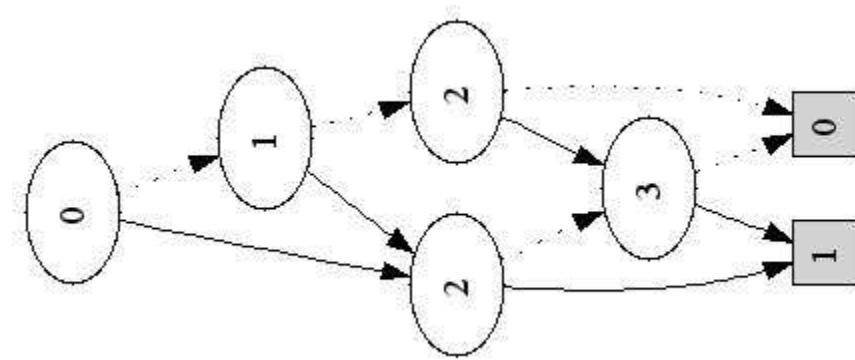

$$2x_0 + 3x_1 + 5x_2 + 5x_3 \geq 7$$

Reduced ordered BDD

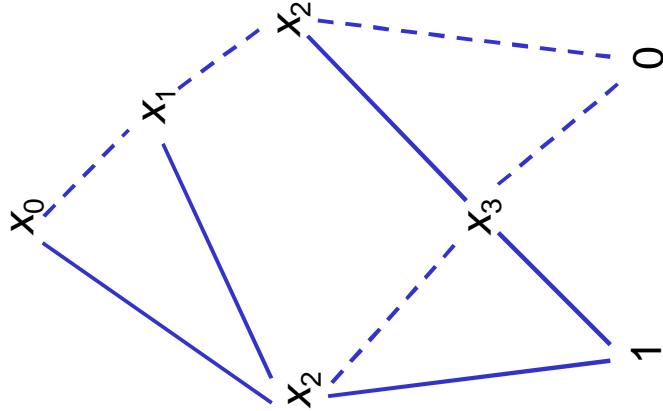

In practice, BDDs are generated **bottom-up**.

First construct a BDD for every constraint and then conjoin the BDDs.

as generated by software
(CLab, BuDDy)

- The BDD for a knapsack constraint can be surprisingly small...

The 0-1 inequality

$$300x_0 + 300x_1 + 285x_2 + 285x_3 + 265x_4 + 265x_5 + 230x_6 + 230x_7 + 190x_8 + 200x_9 + \\ 400x_{10} + 200x_{11} + 400x_{12} + 200x_{13} + 400x_{14} + 200x_{15} + 400x_{16} + 200x_{17} + 400x_{18} \geq 2701$$

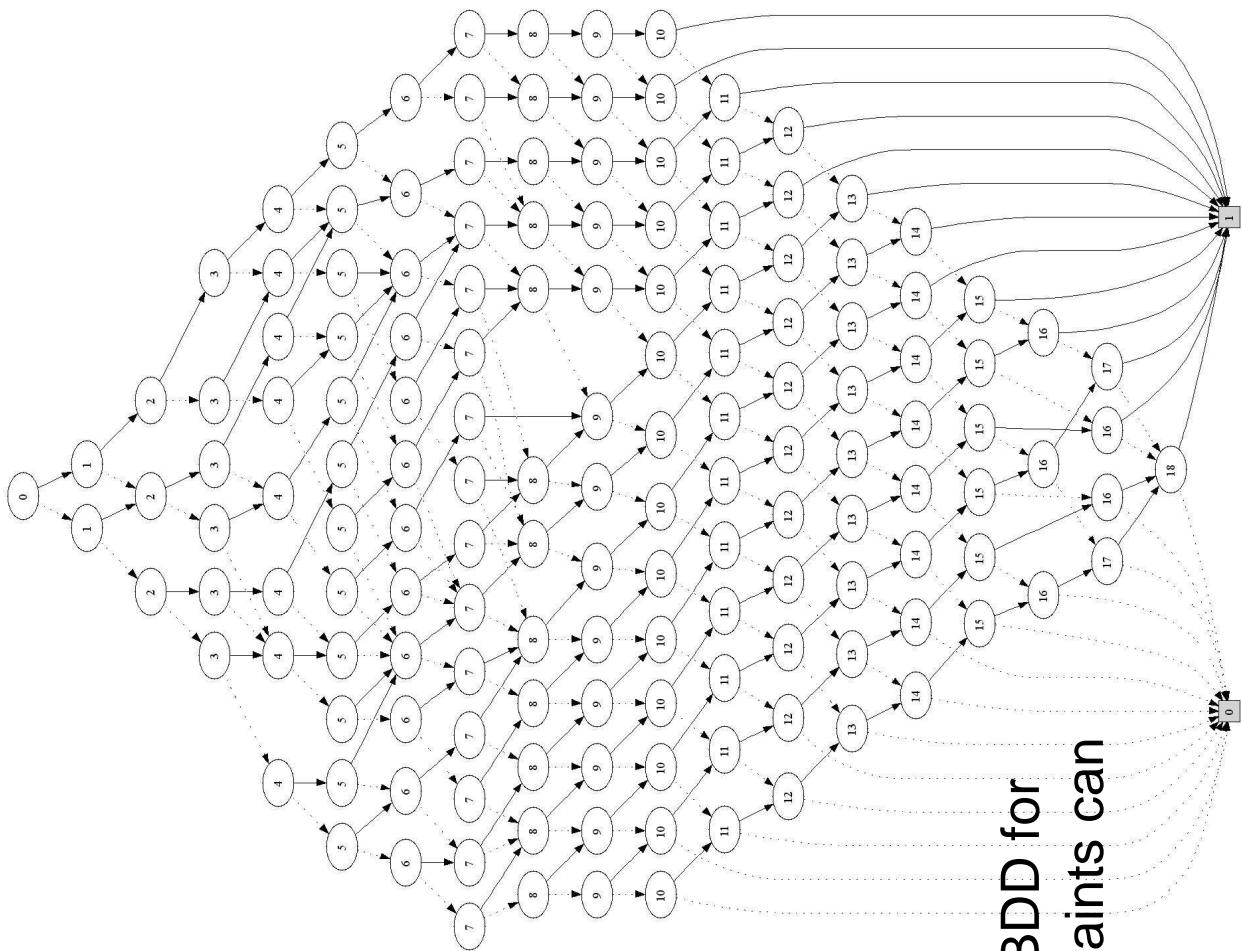

has 117,520 minimal feasible solutions

Or equivalently,

$$300x_0 + 300x_1 + 285x_2 + 285x_3 + 265x_4 + 265x_5 + 230x_6 + 230x_7 + 190x_8 + 200x_9 + \\ 400x_{10} + 200x_{11} + 400x_{12} + 200x_{13} + 400x_{14} + 200x_{15} + 400x_{16} + 200x_{17} + 400x_{18} \leq 2700$$

has 117,520 minimal covers

But its reduced BDD has only 152 nodes...

- However, the BDD for multiple constraints can explode.

Optimization Over BDDs

- We want to solve a 0-1 programming model with an additively separable objective function

$$\min \sum_{j=1}^n c_j(x_j)$$

$$g_i(x) \geq b_i, \quad i = 1, \dots, m$$
$$x_j \in \{0, 1\}, \quad j = 1, \dots, n$$

Can be straightforwardly extended to general integer programming

Optimization Over BDDs

- We want to solve a 0-1 programming model with an additively separable objective function

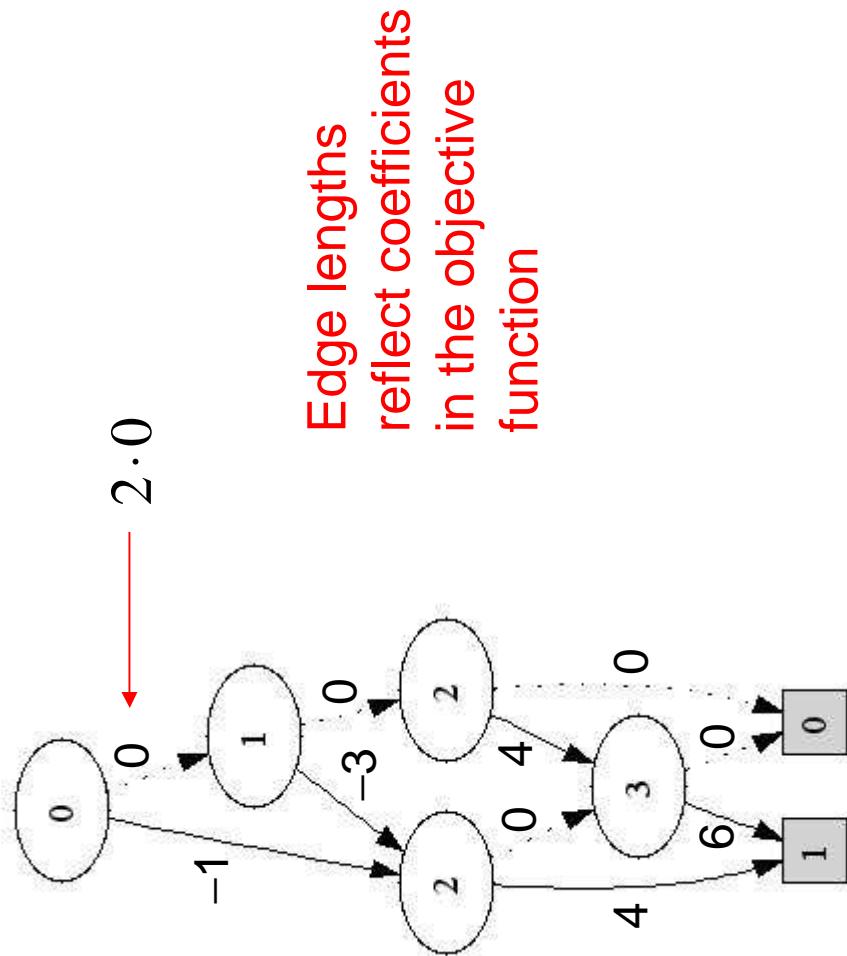

$$\min \sum_{j=1}^n c_j(x_j)$$

$$g_i(x) \geq b_i, \quad i = 1, \dots, m$$
$$x_j \in \{0, 1\}, \quad j = 1, \dots, n$$

Can be straightforwardly extended to general integer programming

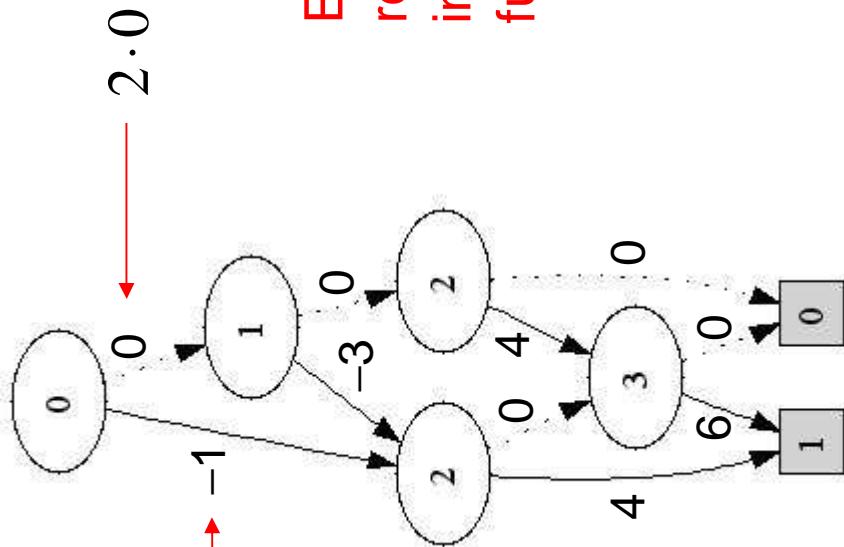

- If we represent the constraints $g_i(x) \geq b_i$ as a BDD, then we can solve the problem by **finding a shortest path** in the BDD with appropriate edge lengths...

$$\min 2x_0 - 3x_1 + 4x_2 + 6x_3 \quad \text{subject to } 2x_0 + 3x_1 + 5x_2 + 5x_3 \geq 7$$

$$\min 2x_0 - 3x_1 + 4x_2 + 6x_3 \quad \text{subject to } 2x_0 + 3x_1 + 5x_2 + 5x_3 \geq 7$$

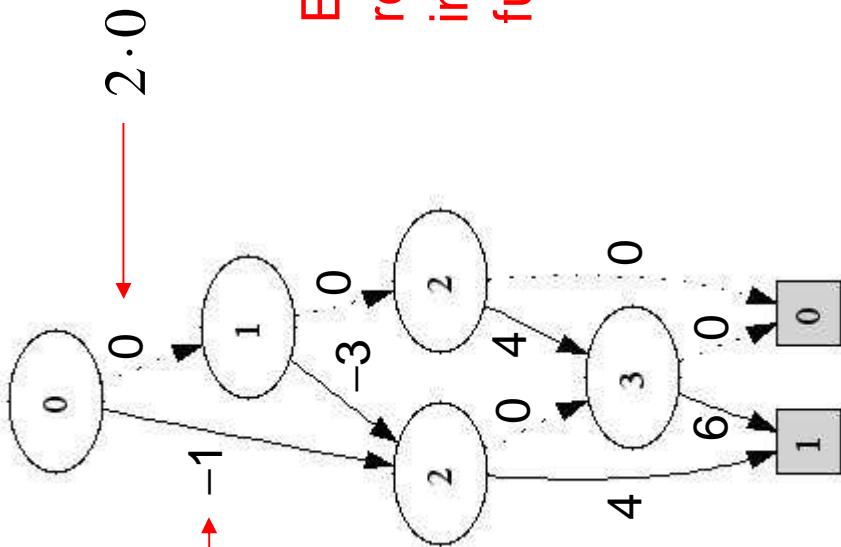

$$2 \cdot 1 + \min_{x_1 \in \{0,1\}} \{-3x_1\}$$

$$\min 2x_0 - 3x_1 + 4x_2 + 6x_3 \quad \text{subject to } 2x_0 + 3x_1 + 5x_2 + 5x_3 \geq 7$$

$$2 \cdot 1 + \min_{x_1 \in \{0,1\}} \{-3x_1\}$$

$$4 \cdot 1 + \min_{x_3 \in \{0,1\}} \{6x_3\}$$

$$\min 2x_0 - 3x_1 + 4x_2 + 6x_3 \quad \text{subject to } 2x_0 + 3x_1 + 5x_2 + 5x_3 \geq 7$$

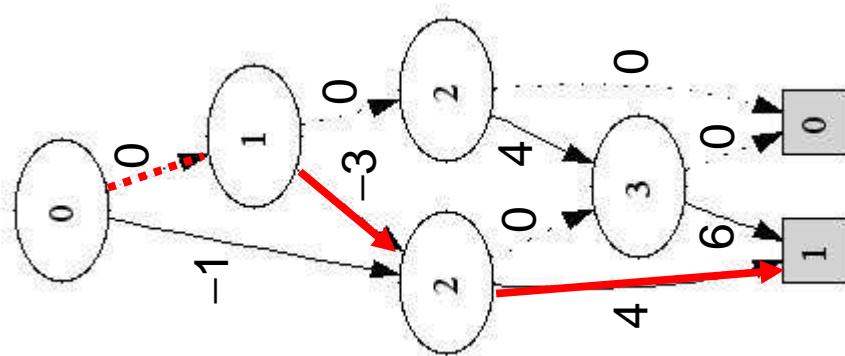

Shortest path has length 1

Optimal solution:

$$(x_0, x_1, x_2, x_3) = (0, 1, 1, 0)$$

Set to minimizing value

We conduct postoptimality analysis by analyzing shortest and near-shortest paths

Cost-Based Domain Analysis

- Consider again

$$\min \sum_{j=1}^n c_j(x_j)$$

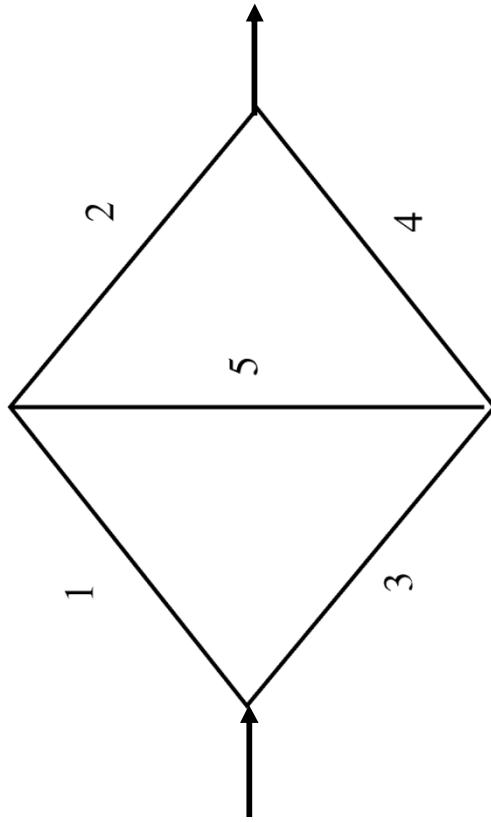

$$g_i(x) \geq b_i, \quad i = 1, \dots, m$$
$$x_j \in \{0, 1\}, \quad j = 1, \dots, n$$

- What values can x_j take without forcing the objective function value above $c_{\text{opt}} + \Delta$?

Optimal value

Example: Network Reliability

- Minimize cost subject to a bound on reliability
 - System of 5 bridges:

$$R = R_1 R_2 + (1 - R_2) R_3 R_4 + (1 - R_1) R_2 R_3 R_4 + R_1 (1 - R_2) (1 - R_3) R_4 R_5 + (1 - R_1) R_2 R_3 (1 - R_4) R_5$$

The problem:

$$\min \sum_j c_j x_j \quad \text{Number of links } j$$

$$R \geq R_{\min}$$

$$\begin{aligned} R &= R_1 R_2 + (1 - R_2) R_3 R_4 + (1 - R_1) R_2 R_3 R_4 \\ &\quad + R_1 (1 - R_2) (1 - R_3) R_4 R_5 + (1 - R_1) R_2 R_3 (1 - R_4) R_5 \\ R_j &= 1 - (1 - r_j)^{x_j}, \quad \text{all } j \\ x_j &\in \{0, 1, 2, 3\} \end{aligned}$$

Set $R_{\min} = 60$ in all examples

$$r = (0.9, 0.85, 0.8, 0.9, 0.95)$$

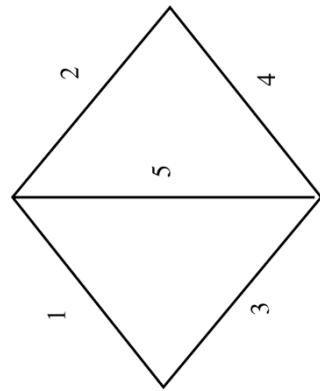

$$c = (25, 35, 40, 10, 60)$$

| $c_{opt} + \Delta$ | x_1 | x_2 | x_3 | x_4 | x_5 | R |

Reducing BDD Growth

- It suffices to use a BDD with the same near-optimal solutions as the original BDD. We assume $\Delta \leq \Delta_{\max}$.

$$B_{\Delta_{\max}}$$

Reducing BDD Growth

- It suffices to use a BDD with the same near-optimal solutions as the original BDD. We assume $\Delta \leq \Delta_{\max}$.

$$Sol = \left\{ \begin{array}{l} \text{feasible} \\ \text{solutions} \end{array} \right\}$$

$$B = \left\{ \begin{array}{l} \text{original} \\ \text{BDD} \end{array} \right\}$$

$$Sol_{\Delta_{\max}} = \left\{ \begin{array}{l} \text{feasible solutions} \\ \text{with value} \leq C_{\text{opt}} + \Delta_{\max} \end{array} \right\}$$

BDD that
 $B_{\Delta_{\max}}$ represents
 $Sol_{\Delta_{\max}}$

Reducing BDD Growth

- It suffices to use a BDD with the same near-optimal solutions as the original BDD. We assume $\Delta \leq \Delta_{\max}$.

$$Sol = \left\{ \begin{array}{l} \text{feasible} \\ \text{solutions} \end{array} \right\}$$

$$B = \left\{ \begin{array}{l} \text{original} \\ \text{BDD} \end{array} \right\}$$

$$Sol_{\Delta_{\max}} = \left\{ \begin{array}{l} \text{feasible solutions} \\ \text{with value} \leq c_{\text{opt}} + \Delta_{\max} \end{array} \right\}$$

BDD that
 $B_{\Delta_{\max}}$ represents
 $Sol_{\Delta_{\max}}$

- Unfortunately, $B_{\Delta_{\max}}$ can be exponentially larger than B .
 - Even though it represents a smaller set of solutions.

Reducing BDD Growth

- It suffices to use a BDD with the same near-optimal solutions as the original BDD. We assume $\Delta \leq \Delta_{\max}$.

$$Sol = \left\{ \begin{array}{l} \text{feasible} \\ \text{solutions} \end{array} \right\}$$

$$B = \overset{\text{original}}{BDD}$$

$$Sol_{\Delta_{\max}} = \left\{ \begin{array}{l} \text{feasible solutions} \\ \text{with value} \leq C_{\text{opt}} + \Delta_{\max} \end{array} \right\}$$

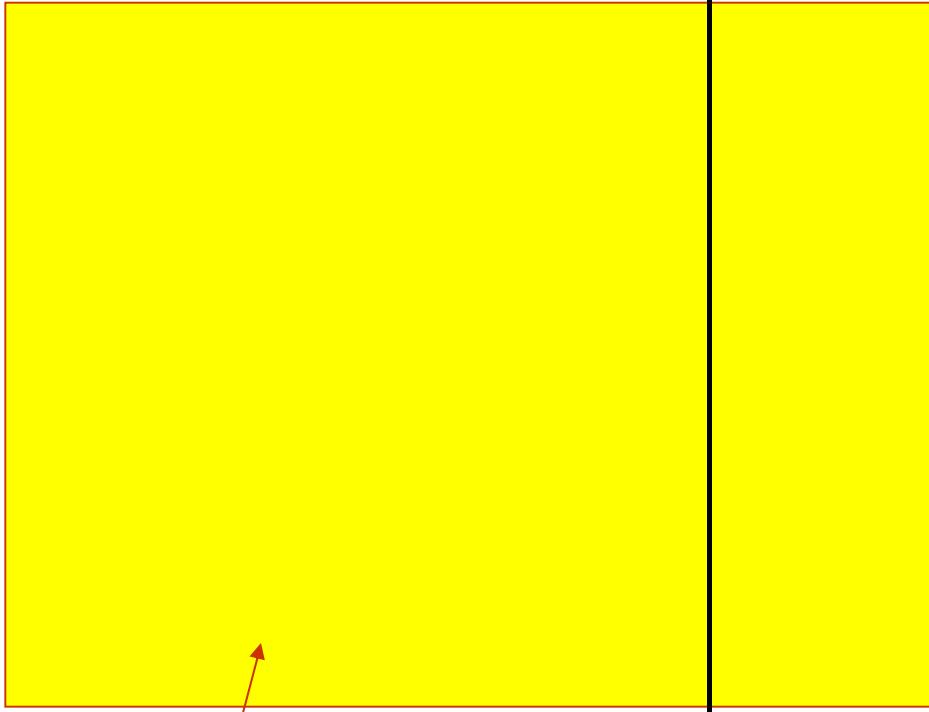

BDD that
 $B_{\Delta_{\max}}$ represents
 $Sol_{\Delta_{\max}}$

- We will construct a **smaller** BDD $B'(\Delta_{\max})$ that is **sound**: $B'(\Delta_{\max})_{\Delta_{\max}} = B_{\Delta_{\max}}$
- It has the same near optimal solutions as B .

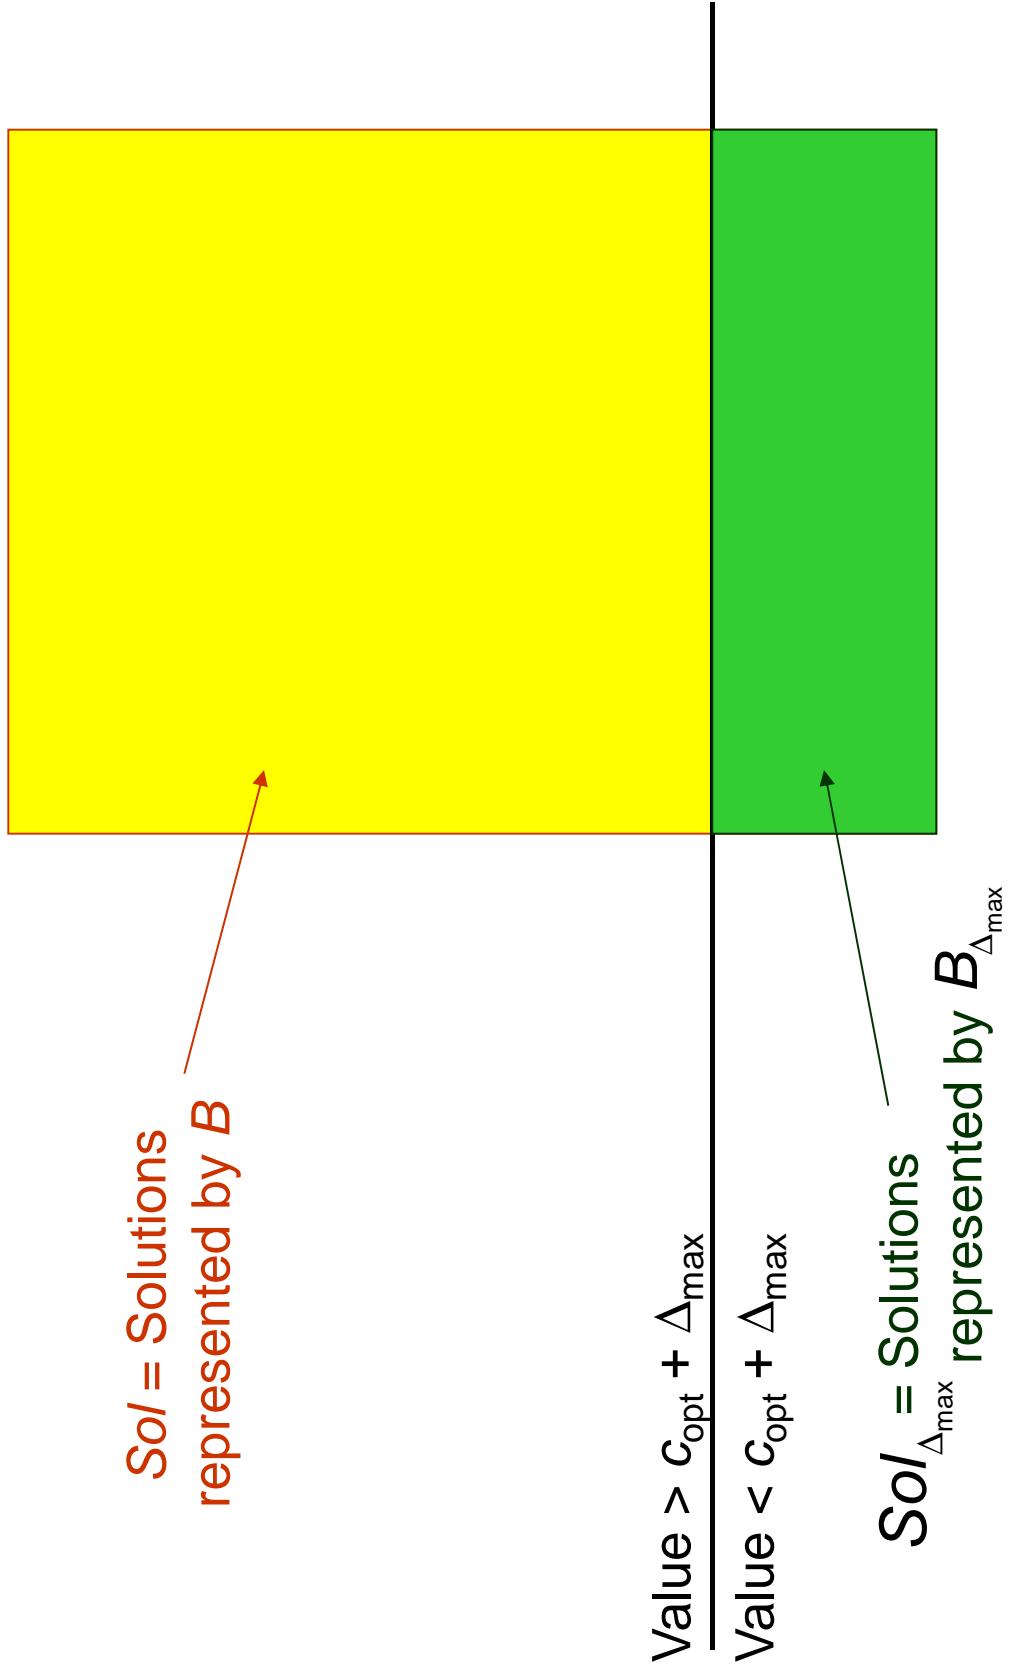

Reducing BDD Growth

$Sol = \text{Solutions}$
represented by B

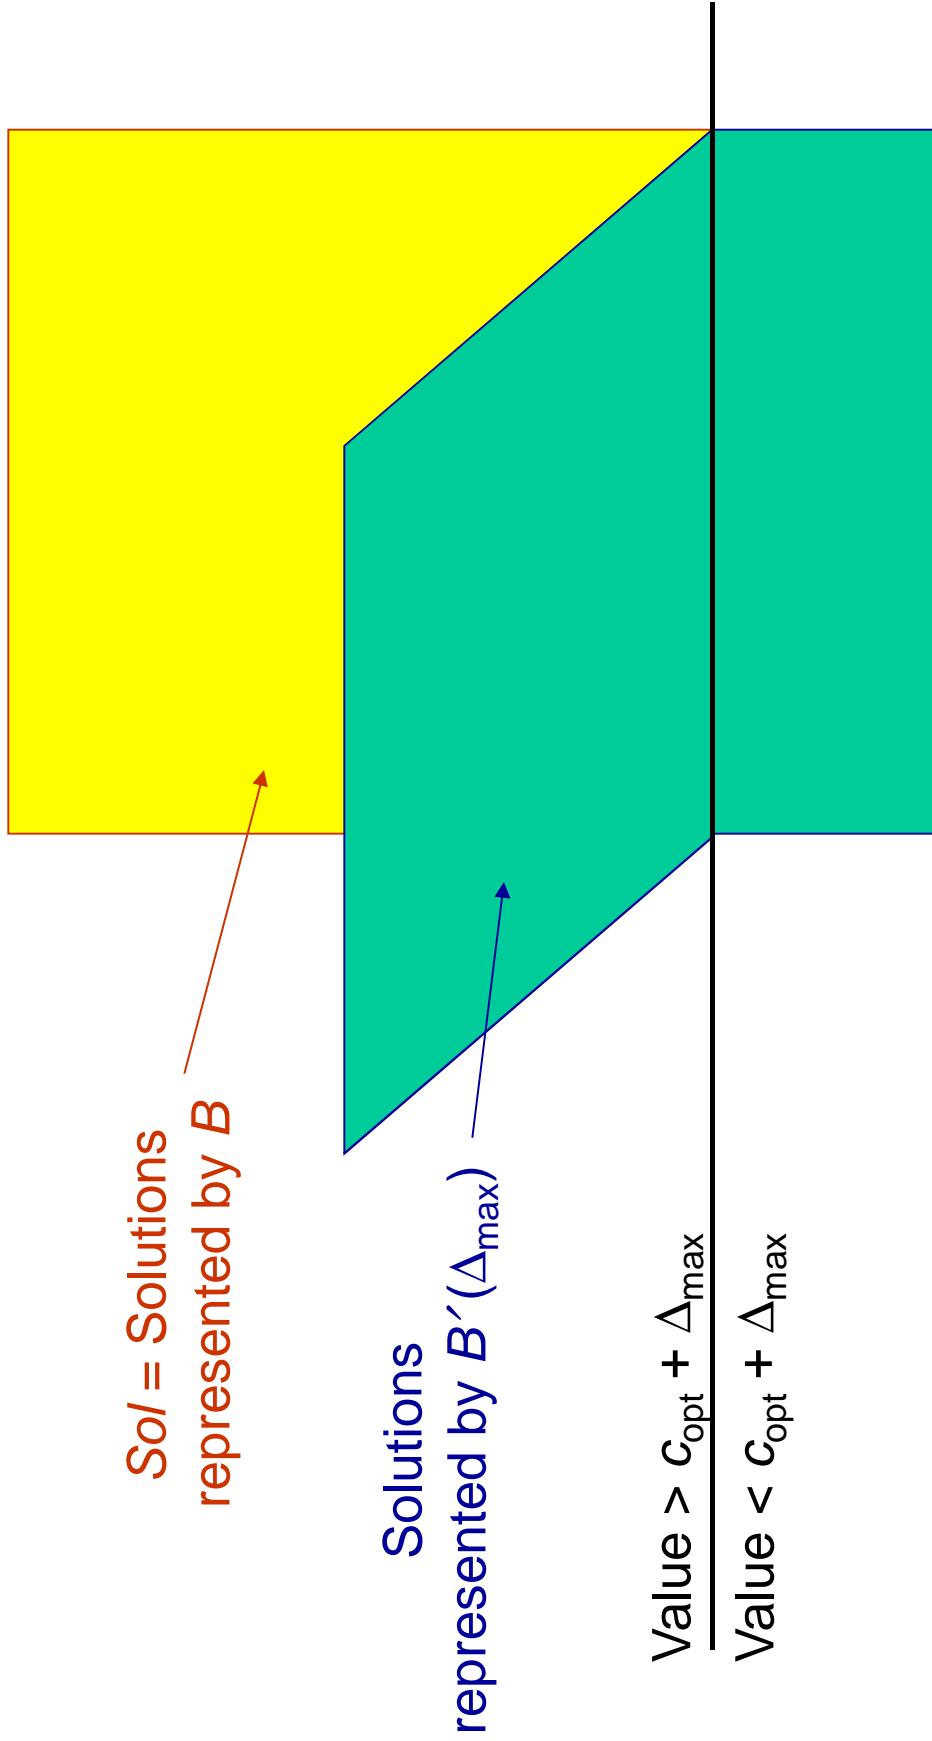

$$\frac{\text{Value} > C_{\text{opt}} + \Delta_{\max}}{\text{Value} < C_{\text{opt}} + \Delta_{\max}}$$

Reducing BDD Growth

Reducing BDD Growth

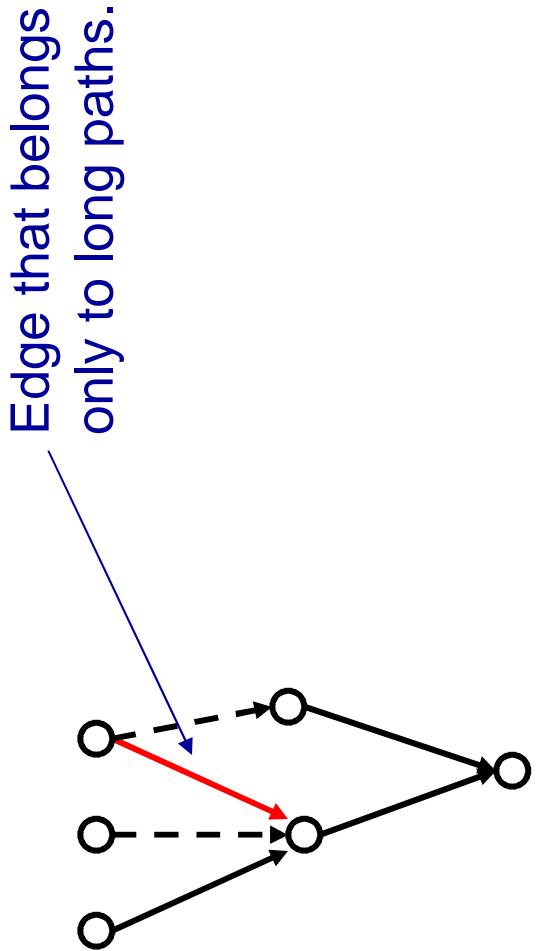

Pruning and Contracting

- We are unaware of a polytime exact method for constructing the **smallest sound BDD**.
- We use two heuristic methods for generating **small sound BDDs** during compilation:
 - Pruning edges
 - Contracting nodes

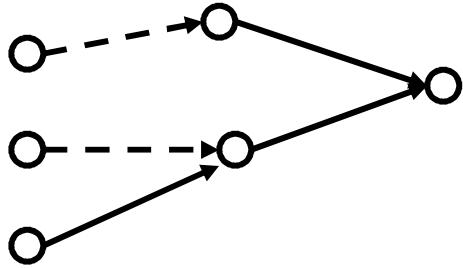

Pruning

- Delete all edges that belong only to paths longer than $C_{\text{opt}} + \Delta_{\text{max}}$.

Pruning

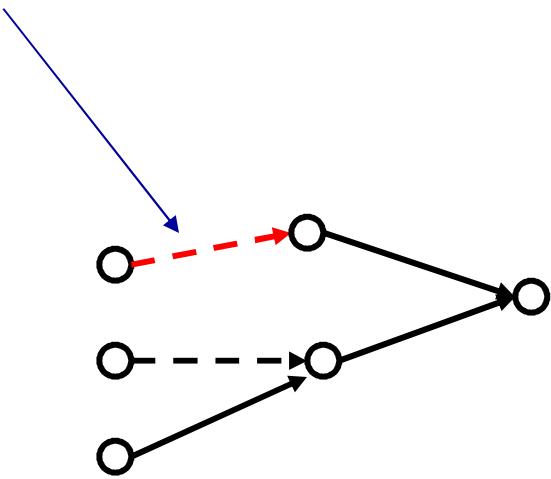

- Delete all edges that belong only to paths longer than $C_{\text{opt}} + \Delta_{\text{max}}$.

Pruning

- Delete all edges that belong only to paths longer than $C_{\text{opt}} + \Delta_{\text{max}}$.

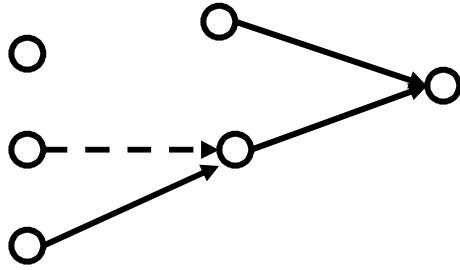

If another edge now belongs only to long paths

Pruning

- Delete all edges that belong only to paths longer than $C_{\text{opt}} + \Delta_{\text{max}}$.

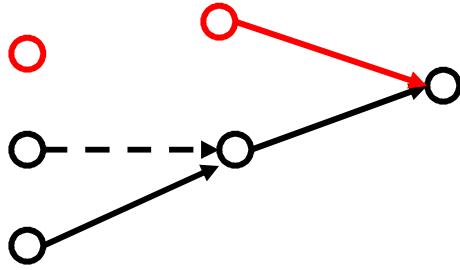

Delete it, too.

Pruning

- Delete all edges that belong only to paths longer than $C_{\text{opt}} + \Delta_{\text{max}}$.

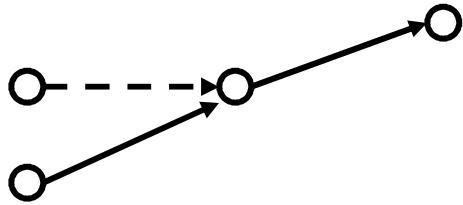

And simplify the BDD.

Pruning

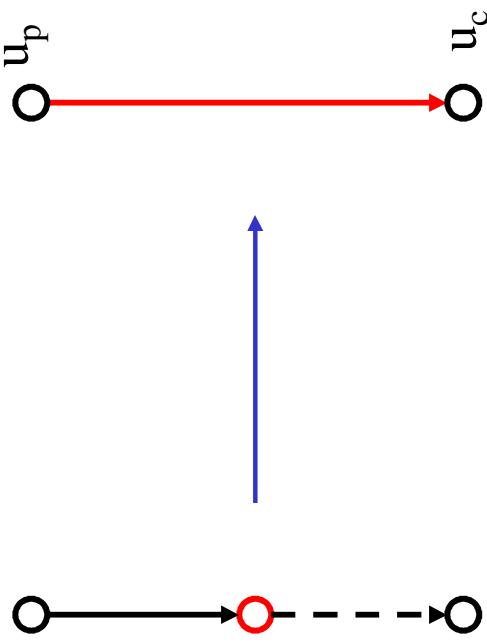

- Delete all edges that belong only to paths longer than $C_{\text{opt}} + \Delta_{\text{max}}$.

And simplify the BDD.

Contracting

- Remove a node if this creates no new paths shorter than $c_{\text{opt}} + \Delta_{\text{max}}$

Experimental Results

- We solve the 0-1 problem

$$\min c x$$

$$Ax \geq b \quad \longrightarrow \quad b_i = \alpha \sum_j A_{ij}$$

$$x \in \{0, 1\}^n$$

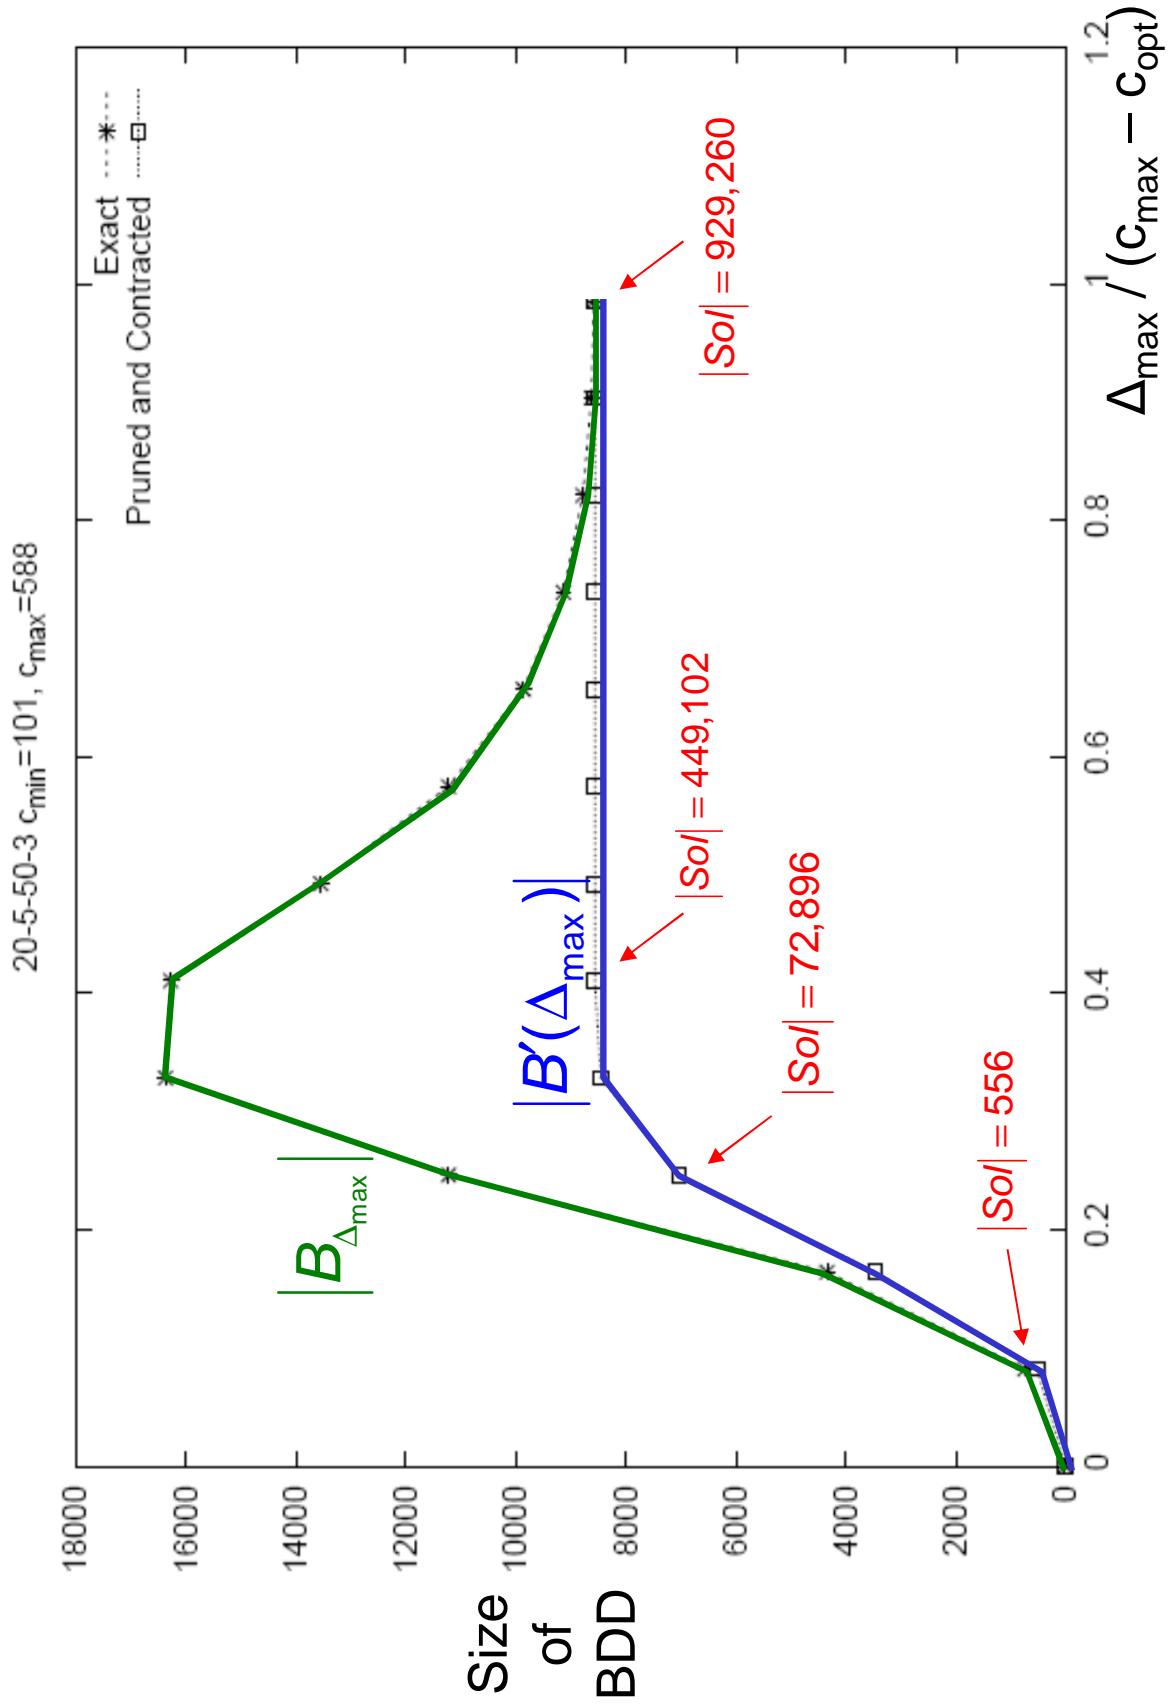

A_{ij} drawn uniformly
from $[0, 1]$

Experimental Results

- 20 variables, 5 constraints
- $C_{\text{opt}} = 101$, $C_{\max} = 588$

Sound BDD

| Δ_{\max} | $ B $ | $ B_{\Delta_{\max}} $ | $ B'(\Delta_{\max}) $ |

Conclusions and Future Work

- Cost-bounded BDDs provide reasonable scalability for BDD-based postoptimality analysis in 0-1 linear programming.

Future work:

- Tests on nonlinear, nonconvex 0-1 problems
 - Nonlinearity, nonconvexity should not be a major factor.
- Extension to general integer problems.
 - Straightforward; a matter of implementation.
- Extension to MILP.
 - ??
